

1.Convert the Temperature You are given a non-negative floating point number rounded to two decimal places celsius, that denotes the temperature in Celsius.You should convert Celsius into Kelvin and Fahrenheit and return it as an array ans = [kelvin, fahrenheit]. Return the array ans. Answers within 10-5 of the actual answer will be accepted. Note that: • Kelvin = Celsius + 273.15 • Fahrenheit = Celsius * 1.80 + 32.00 Example 1: Input: celsius = 36.50 Output: [309.65000,97.70000] Explanation: Temperature at 36.50 Celsius converted in Kelvin is 309.65 and converted in Fahrenheit is 97.70.

```

2.Number of Subarrays With LCM Equal to K Given an integer array nums and an integer k, return the number of subarrays of nums where the least common multiple of the subarray's elements is k.A subarray is a contiguous non- empty sequence of elements within an array.The least common multiple of an array is the smallest positive integer that is divisible by all the array elements. Example 1: Input: nums = [3,6,2,7,1], k = 6 Output: 4 Explanation: The subarrays of nums where 6 is the least common multiple of all the subarray's elements are: - [3,6,2,7,1] - [3,6,2,7,1] - [3,6,2,7,1] - [3,6,2,7,1]

3. Minimum Number of Operations to Sort a Binary Tree by Level You are given the root of a binary tree with unique values. In one operation, you can choose any two nodes at the same level and swap their values. Return the minimum number of operations needed to make the values at each level sorted in a strictly increasing order. The level of a node is the number of edges along the path between it and the root node. Example 1: Input: root = [1,4,3,7,6,8,5,null,null,null,null,9,null,10] Output: 3 Explanation: - Swap 4 and 3. The 2nd level becomes [3,4]. - Swap 7 and 5. The 3rd level becomes [5,6,8,7]. - Swap 8 and 7. The 3rd level becomes [5,6,7,8]. We used 3 operations so return 3. It can be proven that 3 is the minimum number of operations needed.

4. Maximum Number of Non-overlapping Palindrome Substrings You are given a string s and a positive integer k . Select a set of non-overlapping substrings from the string s that satisfy the following conditions: • The length of each substring is at least k . • Each substring is a palindrome. Return the maximum number of substrings in an optimal selection. A substring is a contiguous sequence of characters within a string. Example 1: Input: $s = \text{"abacddbbd"}$, $k = 3$ Output: 2 Explanation: We can select the substrings underlined in $s = \text{"abacddbbd"}$. Both "aba" and "dbbd" are palindromes and have a length of at least $k = 3$. It can be shown that we cannot find a selection with more than two valid substrings. Example 2: Input: $s = \text{"adbcdca"}$, $k = 2$ Output: 0 Explanation: There is no palindrome substring of length at least 2 in the string. Constraints: • $1 \leq k \leq s.length \leq 2000$ • s consists of lowercase English letters

5. Minimum Cost to Buy Apples You are given a positive integer n representing n cities numbered from 1 to n . You are also given a 2D array `roads`, where `roads[i] = [ai, bi, costi]` indicates that there is a bidirectional road between cities a_i and b_i with a cost of traveling equal to $cost_i$. You can buy apples in any city you want, but some cities have different costs to buy apples. You are given the array `appleCost` where `appleCost[i]` is the cost of buying one apple from city i . You start at some city, traverse through various roads, and eventually buy exactly one apple from any city. After you buy that apple, you have to return back to the city you started at, but now the cost of all the roads will be multiplied by a given factor k . Given the integer k , return an array `answer` of size n where `answer[i]` is the minimum total cost to buy an apple if you start at city i . Example 1: Input: $n = 4$, `roads = [[1,2,4],[2,3,2],[2,4,5],[3,4,1],[1,3,4]]`, `appleCost = [56,42,102,301]`, $k = 2$ Output: `[54,42,48,51]` Explanation: The minimum cost for each starting city is the following: - Starting at city 1: You take the path $1 \rightarrow 2$, buy an apple at city 2, and finally take the path $2 \rightarrow 1$. The total cost is $4 + 42 + 4 * 2 = 54$. - Starting at city 2: You directly buy an apple at city 2. The total cost is 42. - Starting at city 3: You take the path $3 \rightarrow 2$, buy an apple at city 2, and finally take the path $2 \rightarrow 3$. The total cost is $2 + 42 + 2 * 2 = 48$. - Starting at city 4: You take the path $4 \rightarrow 3 \rightarrow 2$ then you buy at city 2, and finally take the path $2 \rightarrow 3 \rightarrow 4$. The total cost is $1 + 2 + 42 + 1 * 2 + 2 * 2 = 51$.

6. Number of Unequal Triplets in Array You are given a 0-indexed array of positive integers `nums`. Find the number of triplets (i, j, k) that meet the following conditions:

- $0 \leq i < j < k < \text{nums.length}$
- `nums[i]`, `nums[j]`, and `nums[k]` are pairwise distinct. In other words, `nums[i] != nums[j]`, `nums[i] != nums[k]`, and `nums[j] != nums[k]`. Return the number of triplets that meet the conditions.

Example 1: Input: `nums = [4,4,2,4,3]` Output: 3 Explanation: The following triplets meet the conditions: - (0, 2, 4) because $4 \neq 2 \neq 3$ - (1, 2, 4) because $4 \neq 2 \neq 3$ - (2, 3, 4) because $2 \neq 4 \neq 3$ Since there are 3 triplets, we return 3. Note that (2, 0, 4) is not a valid triplet because $2 > 0$

9.Number of Beautiful Partitions You are given a string s that consists of the digits '1' to '9' and two integers k and minLength . A partition of s is called beautiful if:

- s is partitioned into k non-intersecting substrings.
- Each substring has a length of at least minLength .
- Each substring starts with a prime digit and ends with a non-prime digit. Prime digits are '2', '3', '5', and '7', and the rest of the digits are non-prime.

Return the number of beautiful partitions of s . Since the answer may be very large, return it modulo $10^9 + 7$. A substring is a contiguous sequence of characters within a string.

Example 1: Input: $s = "23542185131"$, $k = 3$, $\text{minLength} = 2$ Output: 3 Explanation: There exists three ways to create a beautiful partition: "2354 | 218 | 5131" "2354 | 21851 | 31" "2354218 | 51 | 31"

Constraints:

- $1 \leq k$, $\text{minLength} \leq s.\text{length} \leq 1000$
- s consists of the digits '1' to '9'.

```

def is_prime(d):
    return d in {2, 3, 5, 7}

def beautifulPartitions(s, k, minLength):
    n = len(s)
    MOD = 10**9 + 7
